December 12th and 13th, San Jose, CA USA

Talk Outline

- Measurement scenario
- Why did we collect this data?
- Wireless signal propagation characteristics
- DASH video measurements
- WebRTC measurements
- Publicly available dataset

Measurement Scenario

- Ran an **adaptive video application** (DASH, WebRTC) while moving at **walking speeds** through the coverage area of a highly **controlled cellular data network**
- Collected metrics that **directly** impact the user (e.g., video rate, frame rate) as well as metrics that **indirectly** impact user (wireless signal quality)

Why did we collect this data?

- Data captured from live wireless networks helps us understand how a real video application performs for an **individual** user using a real network under real conditions

Why did we collect this data?

- Data captured in different radio propagation environments helps us understand how video applications perform in different contexts

Why did we collect this data?

- Data captured from different classes of video applications (video on demand vs. real time communication) helps us understand the challenges of delivering video over wireless networks under different buffering constraints

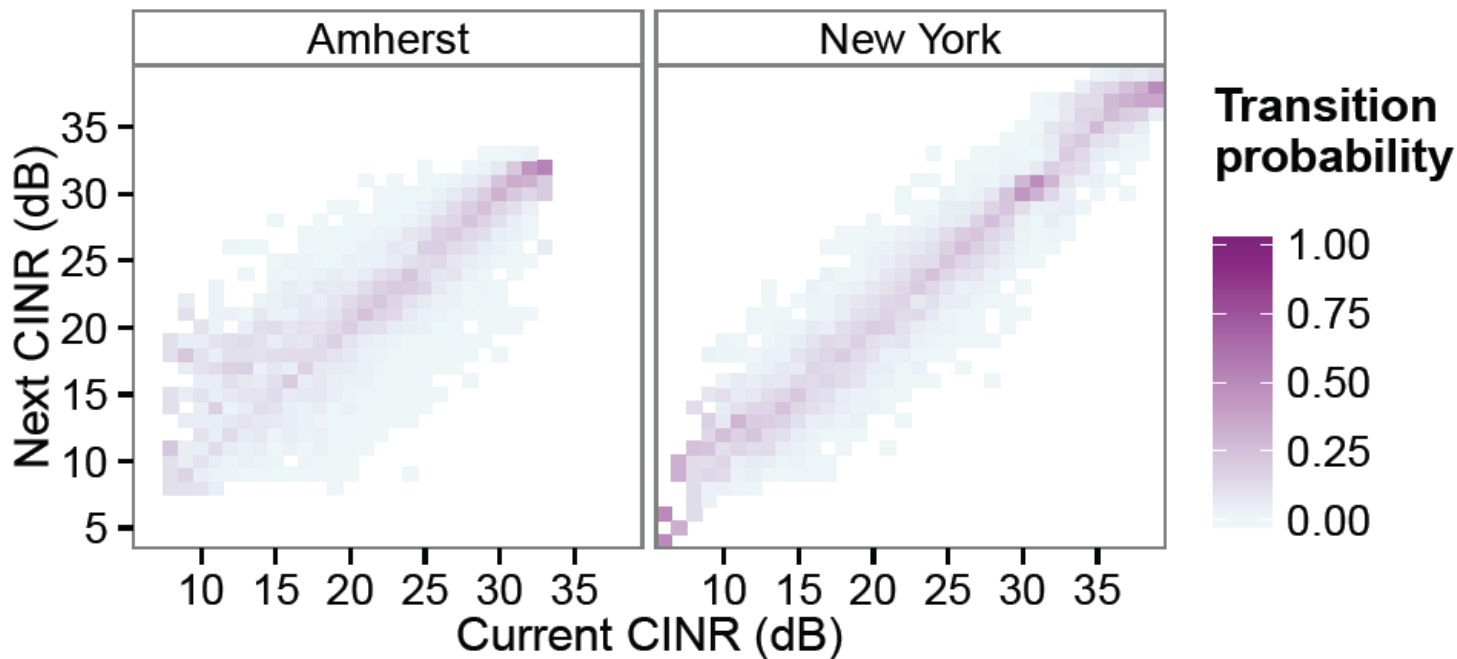

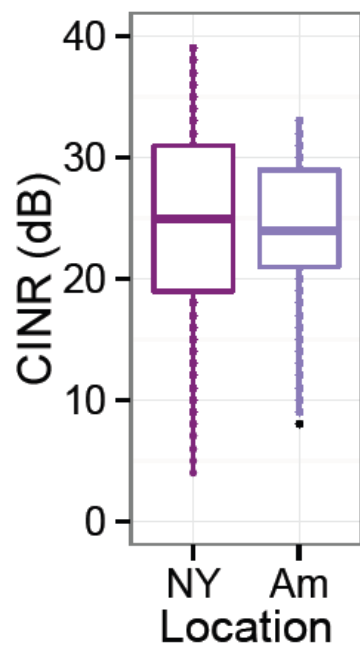

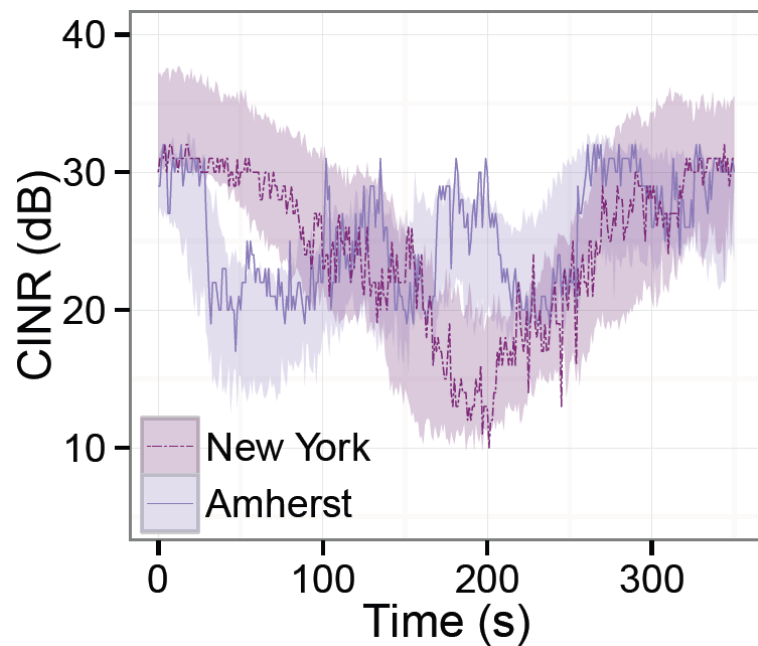

Wireless Signal Propagation Characteristics

UMass Amherst Campus

NYU-Poly Campus

DASH video measurements

DASH download policy

Simple policy (default in VLC DASH plugin):

- Retrieve the highest representation that is less than previous segment download rate,
except
- If buffer is nearing depletion, retrieve the lowest representation

DASH download policy

Why measure such a simple policy?

Tale of Two Cities

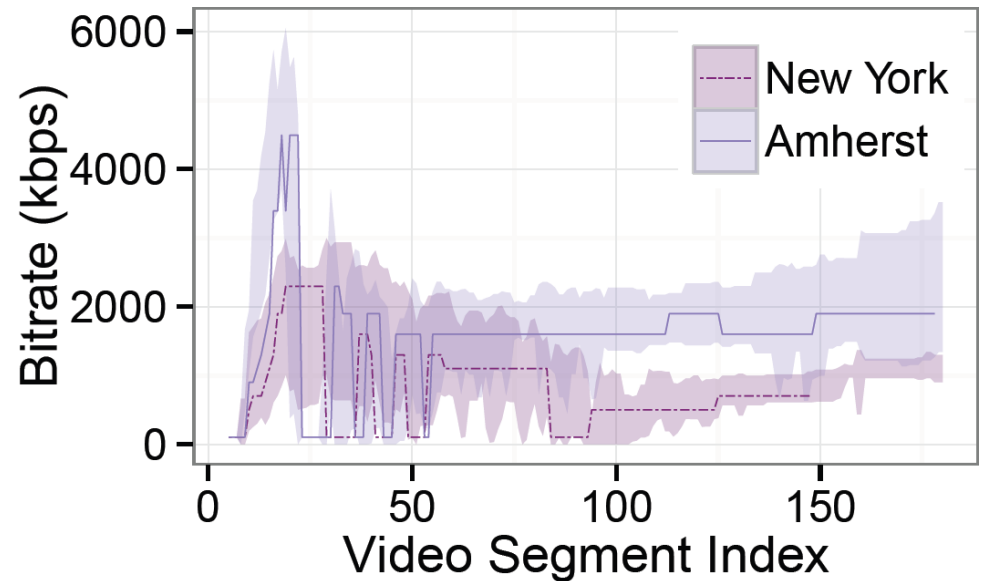

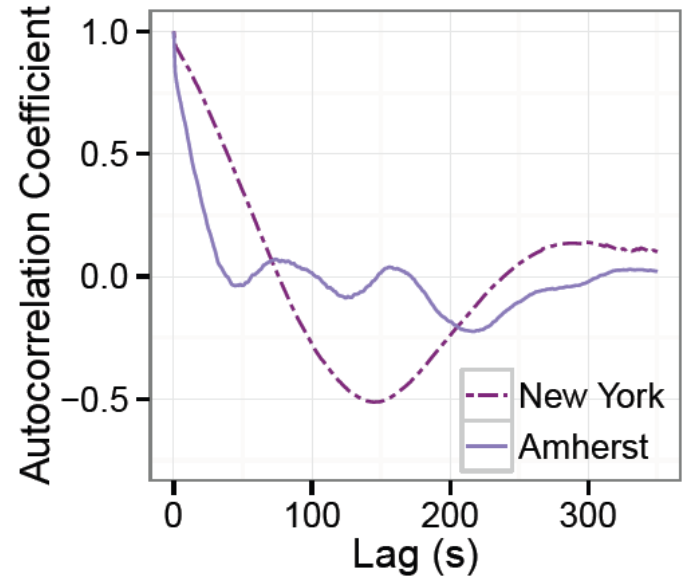

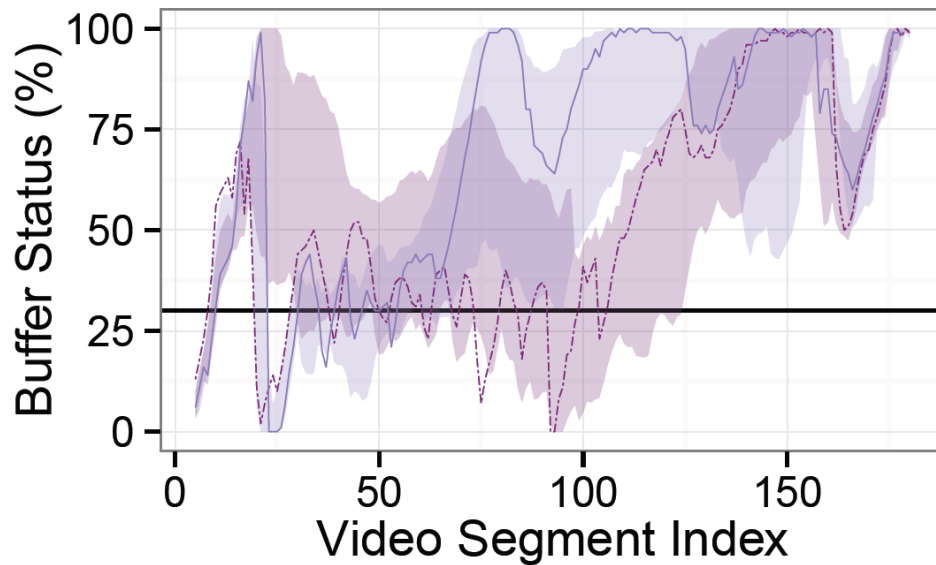

How does an adaptive VOD application react to changes in wireless link quality when

- Wireless signal is consistent for approximately the length of a city block?

vs when

- Wireless signal is consistent for approximately the width of one building?

Tale of Two Cities

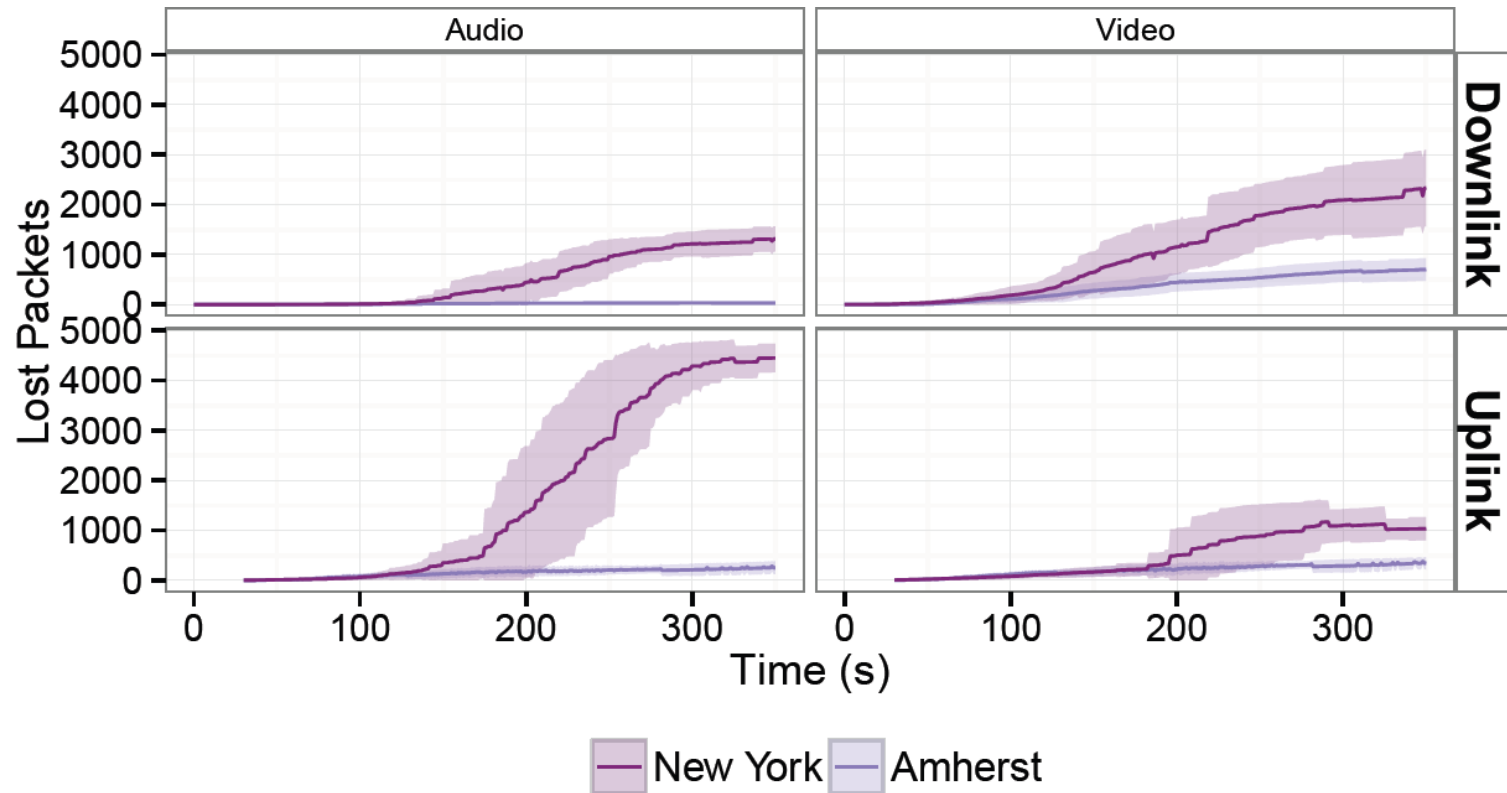

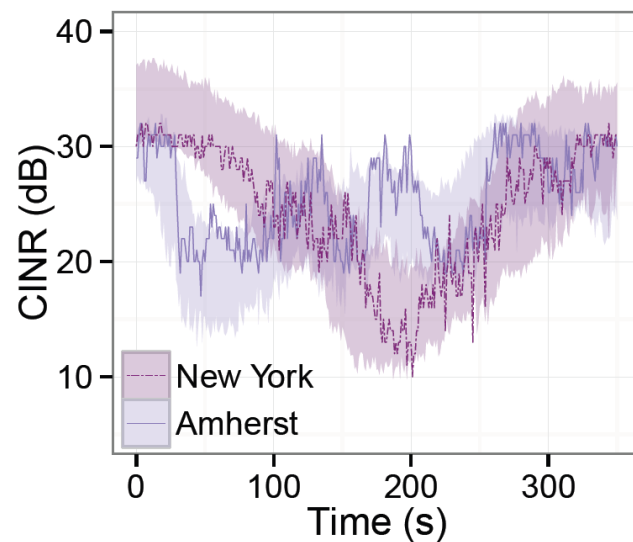

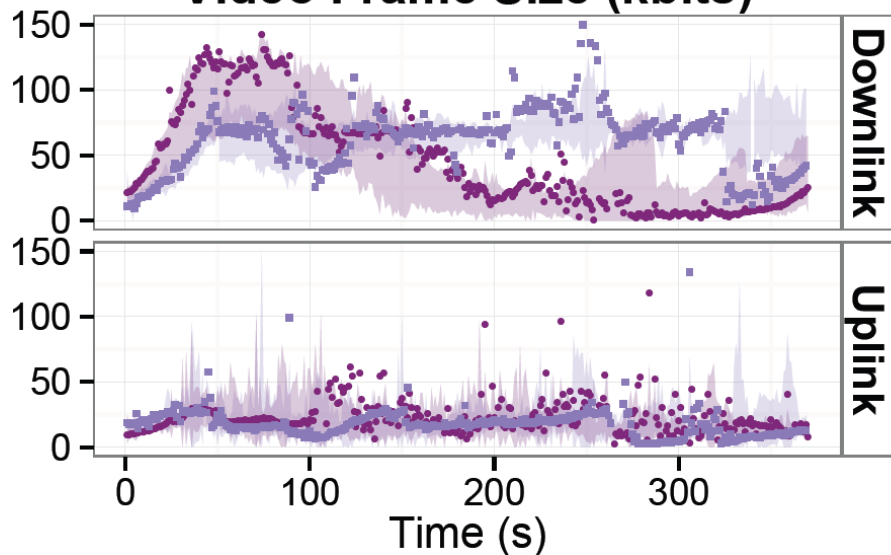

A consistent wireless channel is
a double-edged sword

WebRTC measurements

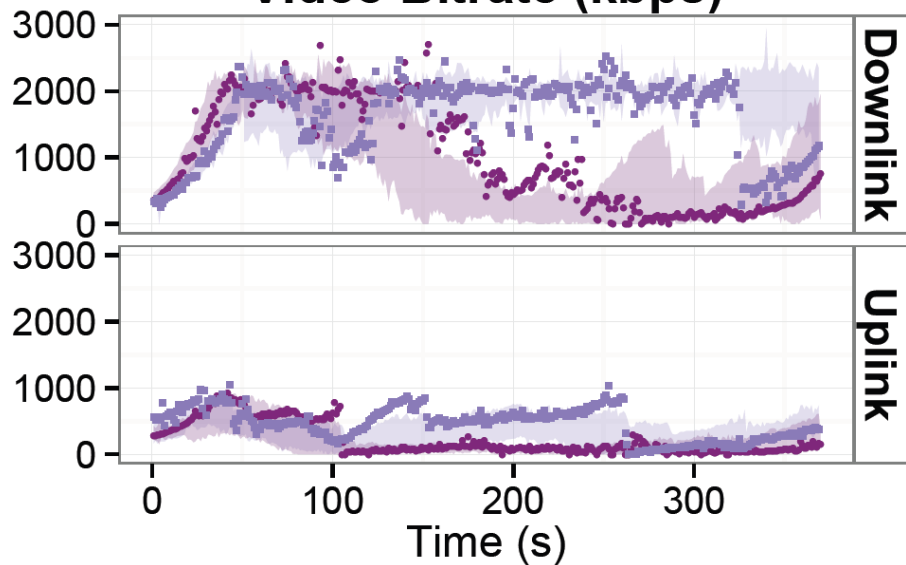

Packet Loss

Video Frame Size (kbits)

Video Bitrate (kbps)

Video Frame Rate (fps)

Challenging network scenarios
remain challenging

CRAWDAD metadata: nyupoly/video (v. 2013-10-21)

This dataset describes measurements from Dynamic Adaptive Streaming over HTTP (DASH) and WebRTC video services, collected over the GENI WiMAX networks at NYU-Poly and UMass Amherst. These measurements are meant to elucidate the experience of an individual user of these services who is moving at walking speeds through the coverage area of a typical cellular network.

[\[xml metadata\]](#)

Note: This metadata was prepared by the CRAWDAD team and verified by the data set (or tool) authors. We have made every effort to ensure its accuracy, but urge all users to consider the metadata and data carefully and be sure that their use in research is consistent with the nature and limitations of the data. We welcome any corrections. This metadata was prepared based on the following reference(s):
