ELASTIC: a Client-side Controller for Dynamic Adaptive Streaming over HTTP (DASH)

Packet Video Workshop - San Jose, CA, USA

12-13 December 2013

L. De Cicco, V. Caldaralo, V. Palmisano, S. Mascolo

Politecnico di Bari, Dipartimento di Ingegneria Elettrica e dell'Informazione

Adaptive Streaming today...

Video distribution platforms use adaptive video streaming, instead of progressive download streaming, to improve the QoE

Multi-bitrate (stream-switching) is the mainstream approach used to implement adaptive streaming over HTTP (MPEG-DASH, HLS)

How does it work?

- ▶ Video is encoded at different bitrate and resolutions, the *video levels*

Level 4, 3500 kbps, 1280x720

Level 3, 2500 kbps, 1280x720

Level 2, 1500 kbps, 640x360

Level 1, 700 kbps, 640x360

Level 0, 300 kbps, 320x180

How does it work?

- ▶ Video is encoded at different bitrate and resolutions, the *video levels*
- ▶ Each video level is divided into segments

How does it work?

- ▶ Video is encoded at different bitrate and resolutions: the *video levels*
- ▶ Each video level is divided into segments
- ▶ For each video segment the stream-switching controller selects the video level according to channel conditions

Leading architectural approach (DASH, HLS)

- ▶ The controller is placed at the client
- ▶ An HTTP server streams the video

Client-side Adaptive Video Streaming system

- ▶ The **HTTP server** sends video through an Internet connection with an end-to-end bandwidth $b(t)$
- ▶ The **Client** receives the video segments at a rate $r(t)$, and stores them in a **playout buffer**.
- ▶ The **measurement** module feeds the controller with the estimated bandwidth $\hat{b}(t)$ and the playout buffer level $q(t)$.
- ▶ The **controller** dynamically selects the video level $l(t)$ by sending a HTTP GET request to the HTTP Server.

The mainstream approach: Buffering – Steady state

The player can be in two different states:

- ▶ **Buffering phase:** Segment requests are performed back-to-back to quickly fill the playout buffer. This state is left when $q(t) > q_T$
- ▶ **Steady-state:** segment requests are spaced to keep the playout buffer level constant.
- ▶ This generates an **ON-OFF traffic pattern:**

ON
when the segments are
downloaded

OFF
when the player is idle

This ON-OFF traffic pattern causes three problems:

1. Unfair bandwidth utilization when many video share a bottleneck [Akhshabi et al, 2012]
2. Flickering of the requested video level [Akhshabi et al, 2012]
3. Video is not able to get the fair share when in the presence of long-lived TCP flows (*downward spiral effect*) [Huang et al, 2012]

ELASTIC

(fEedback Linearization Adaptive STreamIng Controller)

Conventional approach vs Elastic

Conventional approach

Two controllers are used:

- 1) The first selects the video level to match the available bandwidth
- 2) The second controls the playout buffer length by regulating the idle period between the download of two segments (on-off traffic pattern).

Proposed approach

- ▶ Design one controller that throttles the video level $l(t)$ to drive the playout buffer length $q(t)$ to a set-point q_T .
- ▶ This eliminates the ON-OFF traffic pattern

The player is always in ON phase unless $l(t)$ is the highest level and $q > Q_{\max} (> q_T)$

Playout buffer model

Playout buffer model

$$\dot{q}(t) = \frac{r(t)}{l(t)} - d(t)$$

\nearrow Filling rate \nearrow Draining rate

Draining rate

$$d(t) = \begin{cases} 1 & \text{playing} \\ 0 & \text{paused or } q(t) = 0 \end{cases}$$

- ▶ Idea: Based on the playout buffer model, design a feedback control system that computes $l(t)$ to steer $q(t)$ to a threshold q_T
- ▶ Received rate $r(t)$: considered as a (measurable) disturbance since it cannot be manipulated.
- ▶ $l(t)$: output of the controller

$$\dot{q}(t) = \frac{r(t)}{l(t)} - d(t) \quad (1) \quad \text{nonlinear system}$$

We impose a linear second order dynamics for the queue

$$\dot{q}(t) = -k_p q(t) - k_i q_I(t) \quad (2)$$

$$\begin{cases} \dot{q}_I(t) = q(t) - q_T \end{cases} \quad (3) \quad \text{integral error dynamics}$$

The additional dynamics is added to make q converge to q_T at steady state

By equating (1) and (2) and solving for $l(t)$ we get the following law for the stream-switching controller:

$$l(t) = \frac{r(t)}{d(t) - k_p q(t) - k_i q_I(t)}$$

On segment download:

1. $DT = \text{getDownloadTime}();$ /* Downl. Time of last segm. (seconds) */
2. $S = \text{getSegmentSize}();$ /* Last downl. segment Size (bytes) */
3. $q = \text{getQueueLength}();$ /* current queue length (seconds) */
4. $r = h(S/DT);$ /* Harmonic filter of last 5 received rate samples */
5. $ql = ql + DT*(q-qT)$ /* Update integral error */
6. $I = Q(r / (1 - kp*q - ki * ql))$ /* Control law */

The quantizer $Q(x)$ associates to x the highest video level I that is less than x

TESTBED

TESTBED

Server Host

- ▶ Apache as HTTP Server. Connections are persistent.

Client Host

- ▶ NetShaper: we developed this tool to set bandwidth and propagation delays
- ▶ AVP uses GStreamer libraries and supports HLS format. Implements several client-side algorithms as AVP plugins.
- ▶ IPerf is used to inject long-lived TCP flows

Scenarios

S1. Two connections (1 video + 1 video or 1 video + 1 TCP) over a 4Mbps bottleneck

S2. A variable number of video and TCP connections over a 40Mbps bottleneck

Metrics

S1. received video level $I(t)$, received rate $r(t)$, channel utilization.

S2. We consider:

- ▶ r : average received rate
- ▶ U : channel utilization
- ▶ JFI : Jain Fairness Index
- ▶ RB : Rebuffering-ratio
- ▶ n_S : number of video level switches

Video specifics

- ▶ Video encoded at five different bitrates (like Akamai does):

Video level	l_0	l_1	l_2	l_3	l_4
Bitrate (kbps)	300	700	1500	2500	3500
Resolution	320x180	640x360	640x360	1280x720	1280x720

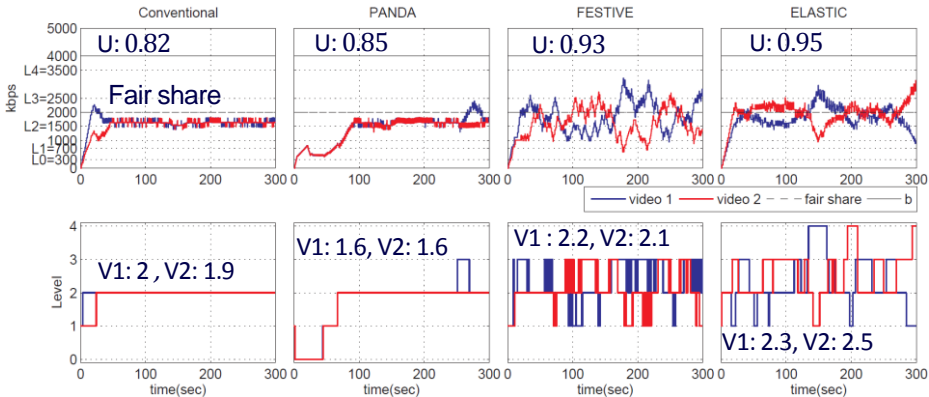

- ▶ Fragment duration of 2s.

- ▶ ELASTIC: $k_p = 1/100$, $k_i = 1/1000$
- ▶ FESTIVE: specifically designed to counteract unfairness in multi-client scenario. Implemented according to the Conext 2012 paper
- ▶ PANDA: proposed by Li et al, dynamically computes the duration of OFF phases based on a control law. We employ the parameters suggested in the paper
- ▶ Conventional: implemented as described in PANDA paper, it selects the video level as a function of the estimated bandwidth

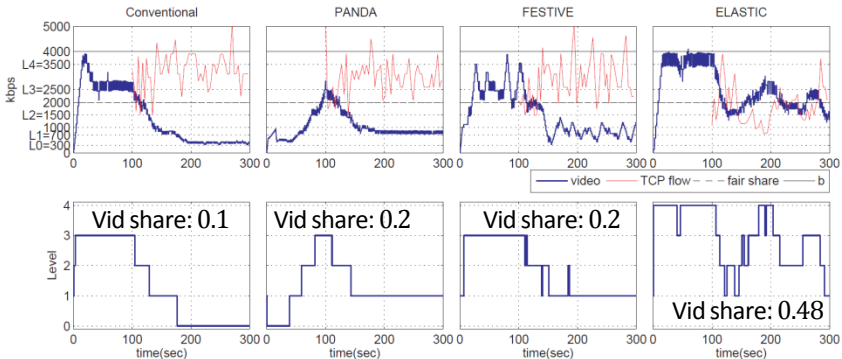

RESULTS

TWO VIDEOS SHARING A 4 Mbps BOTTLENECK

- ▶ Conventional and PANDA: the two videos fairly share the channel with some link underutilization
- ▶ ELASTIC and FESTIVE provide a received video rate that oscillates around the fair share, with an increased number of video level switches.

ONE VIDEO AND ONE TCP FLOW SHARING A 4 Mbps BOTTLENECK

- ▶ Conventional, PANDA and FESTIVE are not able to obtain the fair share when coexisting with a TCP flow (*downward spiral effect*)
- ▶ ELASTIC avoids the downward spiral effect since it does not produce ON-OFF traffic and behaves as the long-lived TCP flow

N_V VIDEOS SHARING A 40 Mbps BOTTLENECK (NO TCP flows)

CHANNEL UTILIZATION

CU for ELASTIC is independent of N_V and around 0.96.

Other algorithms exhibit a lower channel utilization for $N_V = 11$.

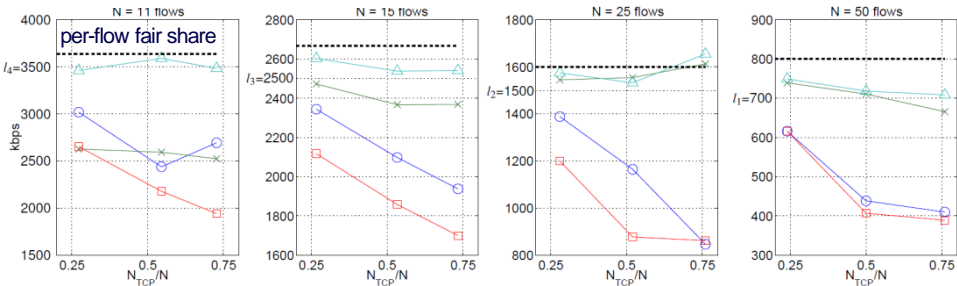

JFI

JFI is in the range [0.96, 1] for all considered algorithms.

AVERAGE VIDEO FLOW RECEIVED RATE

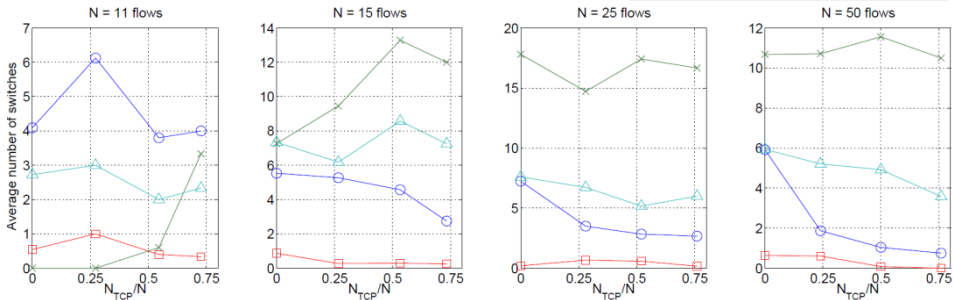

○ Conv.
 × FESTIVE
 □ PANDA
 △ ELASTIC

- ▶ ELASTIC is able to get the fair share regardless of the total number of flows and of the fraction of TCP flows
- ▶ The per-flow average level obtained by PANDA and Conventional decreases when the number of concurrent flow increases

The elimination of the ON-OFF pattern avoids the
 «downward spiral effect»

NUMBER OF PER-FLOW LEVEL SWITCHES

- ▶ ELASTIC performance is comparable to that of Conventional (slightly worse)
- ▶ PANDA provides the best results (under 2 switches) but at the expense of a reduced received video bitrate

50 VIDEOS SHARING A 40 Mbps LINK WITH N_{TCP} TCP FLOWS

- ▶ For $N < 50$ flows we measured RB ratio less than 0.01
- ▶ ELASTIC and Conventional provide RB ratios < 0.05
- ▶ FESTIVE and PANDA exhibit increasing RB ratios.

- ▶ We have proposed ELASTIC a client-side controller which does not generate an ON-OFF traffic pattern
- ▶ An experimental evaluation has shown that ELASTIC is able to get the fair share when competing with TCP long-lived flows
